

Example 2:

Running a Container with a Specific Name

In simple terms giving a container a custom name, by default docker automatically assigns some random name.

For example: When running

```
docker run httpd echo "Hello Name!"
```

vibrant_bardeen

f8a6628462d6

[httpd](#)

“Vibrant_bardeen” → name give to the container by docker.

NOTE:

Image → A docker image is a blueprint/template used to make container

Container → A Docker container is a running instance of an image.
